

how to recognize dental erosion through the basic erosive wear examination; how to conduct a thorough risk assessment with a dietary questionnaire, health history, and measurement of salivary flow rate; how to plan appropriate restorative treatment based on the severity of the erosion, providing recommendations for specific instruments and materials to be used; and how to prevent and/or reduce further erosion after treatment through dietary alterations, dental hygiene measures, and even drug treatments or surgical measures. With ample case studies illustrating the many different presentations of dental erosion and with step-by-step restorative procedures detailing treatment, this book presents the information necessary to diagnose and treat dental erosion in clinical practice.

Herman S. Duiterloo and Pierre-Georges Planché:

Handbook of cephalometric superimposition

Traditional procedures for cephalometric superimposition that are based on the use of periosteally located landmarks or their dependent substitutes are unstable over time. This renders interpretation of pretreatment-to-posttreatment changes unreliable. The structural method of superimposition is the only evidence-based method of superimposition, and it provides individualized, far-reaching insight into growth and treatment changes. The authors provide a critical, in-depth review of the history of cephalometric superimposition and the background and development of the structural method; demonstrate how to apply the structural method; and provide help and instruction for correct interpretation of the resulting superimpositions.
